ArtExtract – Task 1: Convolutional-Recurrent Architecture for Painting Attribute Classification

GSoC 2025 | HumanAI Umbrella | ArtExtract Project

Author: *[Your Name]*

Date: 2025

Dataset: WikiArt via ArtGAN GitHub

Overview

This notebook implements a **CNN-RNN (Convolutional-Recurrent)** architecture to classify paintings by:

- **Style** (e.g., Impressionism, Baroque, Abstract Expressionism)
- **Artist** (e.g., Monet, Picasso, Van Gogh)
- **Genre** (e.g., portrait, landscape, religious painting)

We also perform **outlier detection** to find paintings that do not fit their assigned artist/style/genre labels.

Strategy Summary

Component	Choice	Rationale
CNN backbone	ResNet-50 (pretrained ImageNet)	Strong spatial feature extraction; transfer learning from natural images transfers well to paintings
Recurrent module	Bi-directional GRU	Captures sequential patch relationships; lighter than LSTM; bidirectionality improves global context
Multi-task head	Shared trunk + 3 separate FC heads	Style, Artist, Genre share low-level features; separate heads allow task-specific learning
Patch strategy	4×4 = 16 spatial patches fed as sequence	Enables RNN to model spatial dependencies across image regions
Loss	Weighted cross-entropy (per task)	Handles class imbalance in WikiArt (long-tail distribution)
Outlier detection	Isolation Forest on penultimate embeddings	Model-agnostic; works in high-dimensional embedding space

1. Imports & Environment Setup

In [1]:
```
import os, sys, random, json, time, warnings
from pathlib import Path
from collections import Counter, defaultdict

import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import matplotlib.gridspec as gridspec
import seaborn as sns
from PIL import Image

# PyTorch
import torch
import torch.nn as nn
import torch.nn.functional as F
import torch.optim as optim
from torch.utils.data import Dataset, DataLoader, WeightedRandomSampler
from torch.optim.lr_scheduler import CosineAnnealingLR

# torchvision
import torchvision.models as models
import torchvision.transforms as T

# Scikit-learn (evaluation & outlier detection)
from sklearn.metrics import (
    classification_report, confusion_matrix, f1_score,
    accuracy_score, top_k_accuracy_score, roc_auc_score
)
from sklearn.ensemble import IsolationForest
from sklearn.preprocessing import LabelEncoder
from sklearn.manifold import TSNE
from sklearn.decomposition import PCA

warnings.filterwarnings('ignore')
plt.rcParams['figure.dpi'] = 120
sns.set_theme(style='whitegrid')

print("PyTorch version :", torch.__version__)
print("CUDA available  :", torch.cuda.is_available())
DEVICE = torch.device('cuda' if torch.cuda.is_available() else 'cpu')
print("Device          :", DEVICE)
```

```
PyTorch version : 2.10.0
CUDA available  : False
Device          : cpu
```

2. WikiArt Dataset Setup

The WikiArt dataset (used in ArtGAN) contains ~80,000 paintings across:

- **27 styles** (e.g., Impressionism, Cubism, Baroque ...)

- **195 artists**
- **10 genres** (portrait, landscape, religious painting, genre painting, abstract, cityscape, still life, illustration, nude painting, sketch and study)

Download Instructions

```
# Option A — via ArtGAN repo CSV links
git clone https://github.com/cs-chan/ArtGAN
cd ArtGAN/WikiArt\ Dataset
# Follow README instructions; images are fetched from WikiArt.org

# Option B — Kaggle mirror
kaggle datasets download -d steubk/wikiart
unzip wikiart.zip -d data/wikiart
```

The expected directory layout:

```
data/wikiart/
  ├── Abstract_Expressionism/  (style folder)
  │   ├── picasso_xxx.jpg
  │   └── ...
  ├── Baroque/
  └── ...
```

        FC→27       FC→195       FC→10
```

Why CNN + RNN?

- The CNN extracts rich local texture/colour features per patch (brushstroke style, pigment texture)
- The RNN (Bi-GRU) models *sequential spatial relationships* across the image — a painting's compositional flow (top→bottom, left→right) carries stylistic and genre cues
- The global branch captures holistic composition features the patch sequence might miss
- Multi-task learning acts as a regularizer: style, artist, and genre share a joint representation

6. Evaluation Metrics

Choice & Justification

Metric	Task Suitability	Notes
Top-1 Accuracy	All tasks	Baseline; misleading under class imbalance
Top-5 Accuracy	Artist (195 classes)	Art attribution is inherently uncertain; top-5 reflects real-world usage
Macro F1	Style, Genre	Equal weight to all classes; crucial for long-tail WikiArt distribution
Weighted F1	Artist	Accounts for class frequency differences across 195 artists
Per-class F1 / Confusion Matrix	All	Identifies which styles/genres are confused with each other
Cohen's Kappa	All	Agreement metric robust to chance; meaningful for multi-class

8. Outlier Detection

Outliers are paintings that **do not fit** their assigned label (style / artist / genre) based on the learned embedding space.

Method: Isolation Forest on Embedding Space

1. Extract the **1024-d fused embedding** from the penultimate layer for each test image
2. For each class (e.g., each style), fit an **Isolation Forest** on the in-class embeddings
3. Score each painting — low anomaly scores = outliers
4. Validate with a **t-SNE visualisation** showing outliers in red

Alternative approach (also implemented below): measure **cosine distance from class centroid** in embedding space.

In [11]:
```
def detect_outliers_isolation_forest(embeddings, labels, class_names,
                                     contamination=0.05, task_name='style'):

9. Demo with Synthetic Data (runs without WikiArt)

To demonstrate the pipeline is functional even without the full dataset, we create a small synthetic dataset of randomly coloured "paintings" and run the full pipeline.

In [13]:
```
# ── Synthetic dataset for pipeline validation ──────────────────────────
class SyntheticArtDataset(Dataset):
    """32×32 synthetic images with 5 styles, 10 artists, 4 genres."""
    N_STYLES  = 5
    N_ARTISTS = 10
    N_GENRES  = 4

    def __init__(self, n_samples=800, split='train', patch_rows=4, patch_col
        self.n_samples  = n_samples
        self.patch_rows = patch_rows
        self.patch_cols = patch_cols
        self.patch_h = 8   # 32 / 4
        self.patch_w = 8
        self.samples = [
            (np.random.randint(self.N_STYLES),
             np.random.randint(self.N_ARTISTS),
             np.random.randint(self.N_GENRES))
            for _ in range(n_samples)
        ]
        # ── split ──────────────────────────────────────────────────────
        n_test = int(n_samples * 0.1)
        n_val  = int(n_samples * 0.1)
        if split == 'test':
            self.samples = self.samples[:n_test]
        elif split == 'val':
            self.samples = self.samples[n_test:n_test+n_val]
        else:
            self.samples = self.samples[n_test+n_val:]

        self.style_names  = [f'Style_{i}'  for i in range(self.N_STYLES)]
        self.artist_names = [f'Artist_{i}' for i in range(self.N_ARTISTS)]
        self.genre_names  = [f'Genre_{i}'  for i in range(self.N_GENRES)]

10. Ablation Study Design

To validate the architectural choices, we propose the following ablations:

Model	Change	Hypothesis
CNN-only (ResNet-50)	Remove GRU; use global avg pool	Baseline; no spatial sequence modeling
CNN + LSTM	Replace Bi-GRU with LSTM	Compare recurrent cell types
CNN + Bi-GRU (ours)	Full model	Best sequential spatial understanding
CNN + Transformer	Replace Bi-GRU with 4-head attention	Compare RNN vs attention for patch sequence
No global branch	Remove ResNet-50 global encoder	Ablate holistic features
No patch branch	Remove RNN entirely	Ablate spatial sequence features

In [16]:

```
# ── Ablation: CNN-only baseline (no RNN) ──────────────────────────
class CNNOnly(nn.Module):
    """Ablation baseline: ResNet-50 global features only."""

11. Discussion & Future Work

Key Findings

1. **Style** is the easiest task (fewest classes, most visual consistency). Expected top-1 accuracy ~65-75% on WikiArt.
2. **Artist** classification is hardest (195 classes, some with very few samples). Top-5 accuracy is more informative.
3. **Genre** benefits most from global composition features captured by the CNN branch.
4. **Outliers** tend to cluster at the boundaries between styles in the t-SNE projection.

Identified Outlier Categories

Based on literature and expected model behaviour:

- *Late-period vs early-period* works by the same artist often appear as outliers
- *Cross-genre* paintings (e.g., portraits in a landscape-dominant dataset)
- *Experimental* or transitional works (e.g., Picasso's blue period within Cubism)
- *Misattributed* paintings in the WikiArt metadata

Limitations & Next Steps

Limitation	Proposed Fix
WikiArt metadata noise (incorrect genre/artist labels)	Active learning + human review of outliers
Long-tail class distribution	Few-shot learning heads (ProtoNets) for rare artists
Fixed 4×4 patch grid misses fine details	Adaptive patch extraction (salient region detection)
t-SNE non-deterministic	Use UMAP for stable reproductions

Limitation	Proposed Fix
No uncertainty quantification	Add Monte Carlo Dropout or deep ensembles

Connection to ArtExtract

The learned embeddings from this classifier can directly seed the **hidden painting detection** task:

- Feature distances between spectral bands of a painting correlate with pigment layers
- Outlier embeddings in style-space may indicate under-painting influence

12. Inference on a Single Image

In [17]:
```

13. Conclusions

This notebook presented a full **CNN-RNN multi-task learning pipeline** for classifying paintings by style, artist, and genre, with built-in **outlier detection** to surface mislabelled or atypical works.

Summary of Contributions

- **Architecture**: Dual-branch (global CNN + patch Bi-GRU) with shared multi-task heads
- **Training**: Learnable uncertainty-weighted multi-task loss; weighted sampling for class balance
- **Evaluation**: Top-1/5 accuracy, macro/weighted F1, Cohen's Kappa, per-class analysis
- **Outliers**: Isolation Forest + cosine centroid distance in learned embedding space
- **Visualisation**: t-SNE projections, confusion matrices, per-class F1 bars
- **Ablation**: CNN-only vs CNN+Bi-GRU comparison

This work directly enables the ArtExtract hidden painting detection pipeline, where stylistic outliers may signal under-paintings influencing the visible surface.
